

PATENT COOPERATION TREATY

PCT

NOTIFICATION OF ELECTION

(PCT Rule 61.2)

From the INTERNATIONAL BUREAU

To:

Commissioner
 US Department of Commerce
 United States Patent and Trademark
 Office, PCT
 2011 South Clark Place Room
 CP2/5C24
 Arlington, VA 22202
 ETATS-UNIS D'AMERIQUE
 in its capacity as elected Office

Date of mailing (day/month/year) 12 January 2001 (12.01.01)	
International application No. PCT/EP00/05017	Applicant's or agent's file reference D1544-PCT
International filing date (day/month/year) 31 May 2000 (31.05.00)	Priority date (day/month/year) 04 June 1999 (04.06.99)
Applicant D'UDEKEM D'ACQZ, Xavier, Guy, Bernard et al	

1. The designated Office is hereby notified of its election made:

☒ in the demand filed with the International Preliminary Examining Authority on:
27 November 2000 (27.11.00)

☐ in a notice effecting later election filed with the International Bureau on:

2. The election ☒ was
☐ was not

made before the expiration of 19 months from the priority date or, where Rule 32 applies, within the time limit under Rule 32.2(b).

PATENT COOPERATION TREATY

PCT

INTERNATIONAL SEARCH REPORT

(PCT Article 18 and Rules 43 and 44)

Applicant's or agent's file reference D1544-PCT	FOR FURTHER ACTION see Notification of Transmittal of International Search Report (Form PCT/ISA/220) as well as, where applicable, item 5 below.	
International application No. PCT/EP 00/05017	International filing date (day/month/year) 31/05/2000	(Earliest) Priority Date (day/month/year) 04/06/1999
Applicant D'UDEKEM D'ACQZ, Xavier Guy Bernard		

This International Search Report has been prepared by this International Searching Authority and is transmitted to the applicant according to Article 18. A copy is being transmitted to the International Bureau.

This International Search Report consists of a total of 3 sheets.
☒ It is also accompanied by a copy of each prior art document cited in this report.

1. Basis of the report

- a. With regard to the **language**, the international search was carried out on the basis of the international application in the language in which it was filed, unless otherwise indicated under this item.
- ☐ the international search was carried out on the basis of a translation of the international application furnished to this Authority (Rule 23.1(b)).
- b. With regard to any **nucleotide and/or amino acid sequence** disclosed in the international application, the international search was carried out on the basis of the sequence listing :
- ☐ contained in the international application in written form.
- ☐ filed together with the international application in computer readable form.
- ☐ furnished subsequently to this Authority in written form.
- ☐ furnished subsequently to this Authority in computer readable form.
- ☐ the statement that the subsequently furnished written sequence listing does not go beyond the disclosure in the international application as filed has been furnished.
- ☐ the statement that the information recorded in computer readable form is identical to the written sequence listing has been furnished.

2. ☐ **Certain claims were found unsearchable** (See Box I).

3. ☐ **Unity of invention is lacking** (see Box II).

4. With regard to the title,

- ☒ the text is approved as submitted by the applicant.
- ☐ the text has been established by this Authority to read as follows:

5. With regard to the abstract,

- ☒ the text is approved as submitted by the applicant.
- ☐ the text has been established, according to Rule 38.2(b), by this Authority as it appears in Box III. The applicant may, within one month from the date of mailing of this international search report, submit comments to this Authority.

6. The figure of the drawings to be published with the abstract is Figure No.

- ☒ as suggested by the applicant.
- ☐ because the applicant failed to suggest a figure.
- ☐ because this figure better characterizes the invention.

1

☐ None of the figures.

INTERNATIONAL SEARCH REPORT

International Application No.

P 00/05017

A. CLASSIFICATION OF SUBJECT MATTER

IPC 7 G07F7/10

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC 7 G07F G06F

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

EPO-Internal, WPI Data

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X Y	US 5 491 827 A (HOLTEY THOMAS 0) 13 February 1996 (1996-02-13) column 2, line 66 - column 3, line 13 column 5, line 5 - line 10 column 6, line 56 - line 61 column 7, line 7 - line 18; claim 1; figures 1-3 abstract	1-6, 11, 12 7-10
X A	US 5 442 704 A (HOLTEY THOMAS 0) 15 August 1995 (1995-08-15) column 2, line 57 - column 3, line 34; claim 1; figures 1-4 abstract	1-6, 11, 12 7-10
	--- -/--	

☒ Further documents are listed in the continuation of box C.☒ Patent family members are listed in annex.

* Special categories of cited documents:

"A" document defining the general state of the art which is not considered to be of particular relevance

"E" earlier document but published on or after the international filing date

"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

"O" document referring to an oral disclosure, use, exhibition or other means

"P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

"&" document member of the same patent family

INTERNATIONAL PRELIMINARY EXAMINATION REPORT

(PCT Article 36 and Rule 70)

Applicant's or agent's file reference D1544-PCT	FOR FURTHER ACTION	See Notification of Transmittal of International Preliminary Examination Report (Form PCT/IPEA/416)
International application No. PCT/EP00/05017	International filing date (day/month/year) 31/05/2000	Priority date (day/month/year) 04/06/1999
International Patent Classification (IPC) or national classification and IPC G07F7/10		
Applicant D'UDEKEM D'ACQZ, Xavier Guy Bernard		

1. This international preliminary examination report has been prepared by this International Preliminary Examining Authority and is transmitted to the applicant according to Article 36.

2. This REPORT consists of a total of 6 sheets, including this cover sheet.

- ☒ This report is also accompanied by ANNEXES, i.e. sheets of the description, claims and/or drawings which have been amended and are the basis for this report and/or sheets containing rectifications made before this Authority (see Rule 70.16 and Section 607 of the Administrative Instructions under the PCT).

These annexes consist of a total of 2 sheets.

3. This report contains indications relating to the following items:

- I ☒ Basis of the report
- II ☐ Priority
- III ☐ Non-establishment of opinion with regard to novelty, inventive step and industrial applicability
- IV ☐ Lack of unity of invention
- V ☒ Reasoned statement under Article 35(2) with regard to novelty, inventive step or industrial applicability; citations and explanations supporting such statement
- VI ☐ Certain documents cited
- VII ☒ Certain defects in the international application
- VIII ☒ Certain observations on the international application

Date of submission of the demand 27/11/2000	Date of completion of this report 31.07.2001
Name and mailing address of the international preliminary examining authority:  European Patent Office D-80298 Munich Tel. +49 89 2399 - 0 Tx: 523656 epmu d Fax: +49 89 2399 - 4465	Authorized officer Kampka, A Telephone No. +49 89 2399 2244 

INTERNATIONAL PRELIMINARY EXAMINATION REPORT

International application No. PCT/EP00/05017

I. Basis of the report

1. With regard to the **elements** of the international application (*Replacement sheets which have been furnished to the receiving Office in response to an invitation under Article 14 are referred to in this report as "originally filed" and are not annexed to this report since they do not contain amendments (Rules 70.16 and 70.17)*):

Description, pages:

1-17 as originally filed

Claims, No.:

1-10 as received on 29/06/2001 with letter of 26/06/2001

Drawings, sheets:

1/18-18/18 as originally filed

2. With regard to the **language**, all the elements marked above were available or furnished to this Authority in the language in which the international application was filed, unless otherwise indicated under this item.

These elements were available or furnished to this Authority in the following language: , which is:

- ☐ the language of a translation furnished for the purposes of the international search (under Rule 23.1(b)).
- ☐ the language of publication of the international application (under Rule 48.3(b)).
- ☐ the language of a translation furnished for the purposes of international preliminary examination (under Rule 55.2 and/or 55.3).

3. With regard to any **nucleotide and/or amino acid sequence** disclosed in the international application, the international preliminary examination was carried out on the basis of the sequence listing:

- ☐ contained in the international application in written form.
- ☐ filed together with the international application in computer readable form.
- ☐ furnished subsequently to this Authority in written form.
- ☐ furnished subsequently to this Authority in computer readable form.
- ☐ The statement that the subsequently furnished written sequence listing does not go beyond the disclosure in the international application as filed has been furnished.
- ☐ The statement that the information recorded in computer readable form is identical to the written sequence listing has been furnished.

4. The amendments have resulted in the cancellation of:

- ☐ the description, pages:
- ☒ the claims, Nos.: 11, 12

INTERNATIONAL PRELIMINARY EXAMINATION REPORT

International application No. PCT/EP00/05017

☐ the drawings, sheets:

5. ☐ This report has been established as if (some of) the amendments had not been made, since they have been considered to go beyond the disclosure as filed (Rule 70.2(c)):

(Any replacement sheet containing such amendments must be referred to under item 1 and annexed to this report.)

6. Additional observations, if necessary:

V. Reasoned statement under Article 35(2) with regard to novelty, inventive step or industrial applicability; citations and explanations supporting such statement

1. Statement

Novelty (N)	Yes:	Claims	1 - 10
	No:	Claims	
Inventive step (IS)	Yes:	Claims	1 - 10
	No:	Claims	
Industrial applicability (IA)	Yes:	Claims	1 - 10
	No:	Claims	

2. Citations and explanations
see separate sheet

VII. Certain defects in the international application

The following defects in the form or contents of the international application have been noted:
see separate sheet

VIII. Certain observations on the international application

The following observations on the clarity of the claims, description, and drawings or on the question whether the claims are fully supported by the description, are made:
see separate sheet

**INTERNATIONAL PRELIMINARY
EXAMINATION REPORT - SEPARATE SHEET**

International application No. PCT/EP00/05017

Re Item V

Reasoned statement under Art. 35(2) with regard to novelty, inventive step or industrial applicability; citations and explanations supporting such statement

Reference is made to the following documents:

D1: US-A-5 491 827 (HOLTEY THOMAS O) 13 February 1996 (1996-02-13)
D2: US-A-5 442 704 (HOLTEY THOMAS O) 15 August 1995 (1995-08-15)
D3: US-A-4 982 378 (MATSUSHITA TSUYOSHI) 1 January 1991 (1991-01-01)
D4: US-A-4 566 082 (ANDERSON RUSSELL Y) 21 January 1986 (1986-01-21)
D5: US-A-3 972 028 (WEBER GERALD ET AL) 27 July 1976 (1976-07-27)
D6: EP-A-0 347 321 (SGS THOMSON MICROELECTRONICS) 20 December 1989 (1989-12-20)

1. Document D1 discloses (see the abstract; col. 2, line 66 - col. 3, line 13; col. 6, lines 56 - 66 and col. 8, line 54 - col. 10, line 22) a card memory device in which there is direct data access to the memory units via a bus and the data access is not through a microprocessor. Thus there is no read in and read out from the card to and from the memory units which passes through the microprocessor. D1 has an interface logic 104 through which all data passes to and from the card. the various microprocessors are able to control this flow by influencing access to the memories but the data does not pass through these microprocessors as such.

D2 discloses a prior art with similar architecture, see col. 2, line 57 - col. 3, line 34.

2. Starting from D1 (or D2) the problem is to enhance the security.
3. According to claim 1, the device has the advantage that total control of the data and the addressing of the memory devices is possible by the microprocessor: "the microprocessor is adapted for routing through all data and address information sent to and sent by the card memory device". All the data to be written into or read out of the memory units from or to the external passes through the microprocessor. Hence, no external device obtains access to any of the address information of the memories.

Claim 9 defines a method corresponding to claim 1.

4. The applicant in his letter dated 26.06.2001 argued that an assumption that the interface logic in D1 could be replaced by a microprocessor would be based on ex post facto analysis, as there is no indication in D1 or the other prior art documents to do this. In comparison with the prior art, the invention defined in claims 1 and 9 starts from a different principle, namely that of preventing direct memory access via bus combined with access control.
5. Therefore, claims 1 and 9 meet the criteria set forth in Art. 33(1) PCT with respect to the available prior art. Claims 2 - 8 and 10 relate to preferred embodiments and therefore also meet these criteria.

Re Item VII

Certain defects in the international application

To meet the requirements of Rule 5.1(a)(ii) PCT, documents D1 and D2 should have been identified and the relevant background art disclosed therein should have been briefly discussed.

Reference signs in parentheses should have been inserted in all the claims to increase their intelligibility, Rule 6.2(b) PCT. This applies to both the preamble and characterising portion.

Re Item VIII

Certain observations on the international application

The description should have been adapted to the new set of claims. Features are indicated in the description as belonging to the invention, which are not defined in independent claims 1 and 9, see the present summary of the invention on pages 3 - 5 and page 17, lines 23 - 31. The invention comprises the features of the independent claim, i.e. all essential, non-facultative features. Preferred embodiments comprise facultative features, i.e. features of the dependent claims

**INTERNATIONAL PRELIMINARY
EXAMINATION REPORT - SEPARATE SHEET**

International application No. PCT/EP00/05017

or features only defined in the description. Different definitions of the invention in the description and in the independent claims which could lead to unclarity which features are essential for the invention if the claims are read together with the description should have been avoided (Art. 6 PCT with Rule 6.3 b) PCT).

Amended claims

1. A card memory device (20) having an input/output device (1) and having embedded:
a microprocessor (2);
5 a plurality of memory units (5-12, 16, 17) for storage of digital data, and
a selecting device (3, 4) for selecting one of the memory units (5-12, 16, 17) and for
routing the address information and data to and/or from the selected memory unit (5-12,
16, 17), characterized in that:
the microprocessor (2) is interposed between the input/output device (1) and the
10 selecting device (3, 4) and the microprocessor is adapted for:
 routing through all data and address information sent to and sent by the card
 memory device (20), and
 for supplying address information which relates to the data sent to each selected
 memory unit (5-12, 16, 17).
15
2. The card memory device according to claim 1, wherein the addressing scheme for
each memory location of a memory unit includes a parallel and a serial portion.
3. The card memory device according to claim 2, wherein a parallel port of the selecting
20 device is connected to a parallel port of the microprocessor for receiving the parallel
portion of a card memory address.
4. The card memory according to claim 2 or 3, wherein a first serial port of the selecting
device is connected to a serial port of the microprocessor for receiving the serial portion
25 of a card memory address.
5. The card memory device according to any of claims 2 to 4, wherein the selecting
device has a plurality of second serial ports, one connected to each memory unit via a
serial bus and the parallel address portion defines one of the second serial ports of the
30 selecting device.

2

6. The card memory device according to any previous claim, wherein the memory capacity is at least 1 Mbytes.

7. The card memory device according to any previous claim, further comprising a first set of surface contacts including a ground contact, a power source contact and a data input and/or output contact, and the first set corresponding to a second set of contacts in a card memory device reader, the ground contact of the first set being arranged to ground any contact of the second set before this reader contact makes contact with any of the power and/or data contacts.

10

8. The card memory device according to claim 7, wherein the ground contact on the card memory device surrounds the data contact on three sides.

9. A method of using a card memory device having an input/output device and having embedded therein a microprocessor and a plurality of memory units for storage of digital data, the method comprising:
selecting one of the memory units; and
routing address information and data to and/or from the selected memory unit, characterized by
routing through the microprocessor all data and address information set to and sent by the card memory device; and
supplying address information from the microprocessor relating to the data sent to each selected memory unit.

10. The method according to claim 9, wherein the card memory device is a card memory device according to any of the claims 1 to 8.

(54) Title: CARD MEMORY APPARATUS

(57) Abstract: The present invention includes a card memory device (20) comprising a microprocessor (2), a plurality of memory units (5-12) for storage of digital data, the memory units (5-12) being embedded in the card memory device (20). A selecting device (3, 4) is provided for selecting one of the memory units (5-12) and for routing address information and data to the selected memory unit (5-12), both the microprocessor (2) and the selecting device (3, 4) being embedded in the card memory device (20). The card memory device integrates components into a thin flexible memory card with surface contacts (1) so that the components can cooperate as a compact unit providing environmental sealing and secure access to several Mbytes of digital data. A specially designed set (1) of contacts (21-25) are also described which reduce the risk of electrostatic discharge. The card memory device (20) may be used for secure control of a personal computer.

For two-letter codes and other abbreviations, refer to the "Guidance Notes on Codes and Abbreviations" appearing at the beginning of each regular issue of the PCT Gazette.

CARD MEMORY APPARATUS

The present invention relates to card memories, particularly to the provision of memory on a flexible card having an input/output device such as surface contacts. The memory
5 may be read/writable and non-volatile.

TECHNICAL BACKGROUND OF THE INVENTION

There is a general requirement for storing data, particularly personal data, for use in various types of transactions such as health insurance, telephone calls, paying for
10 mass transit, as well as in "set-up" boxes for satellite video or pay TV, etc. One way of doing this is digitally. For everyday personal use, such a digital data store should be compact, e.g. about as big as a conventional credit card, and must be able to:

- 1) withstand moisture - at least quick immersion and/or high humidity levels,
- 2) withstand dust particles encountered in handbags, coat pockets and wallets without
15 loss of performance,
- 3) withstand bending without failure, e.g. when forced into a wallet,
- 4) be UV resistant,
- 5) withstand electromagnetic and magnetic fields produced by common household devices as well as small magnets without loss of data,
- 20 6) to be manufactured in high volumes at a low manufacturing cost.

There are several types of known transportable devices for storing digital data. The ubiquitous "floppy" diskette provides reliable access to 1.44 Mbyte of data storage. Although relatively robust, diskettes still require careful handling and are sensitive to dust and bending. Developments of higher storage capacity have been
25 introduced, for example ZIP drives with capacities over 100 Mbytes. Removable hard drives such as supplied by Syquest Corporation, USA allow the storage of many hundreds of megabytes of data. Neither diskettes nor replaceable hard drives are flexible. They are sensitive to mechanical damage and dust and are not suitable for carrying in a coat pocket, in a wallet or in a lady's handbag for daily use. They are
30 generally not used with terminals, e.g. Point-of Sale (POS) terminals for financial purposes or with other forms of data transfer, e.g. for use as identification of membership of a health insurance organization.

In addition so-called PCMCIA memory cards are known which include a 68 pin connector at one end, are usually electromagnetically shielded with metal layers on both sides, are not flexible and are about 5mm thick. PCMCIA cards with the ability to store several megabytes of data are known, for instance, from EP 596 276, US 5,293,424, US 5,671,367, US 5,875,480. PCMCIA cards provide a high quality connector and metallic screening suitable for installation in lap-tops and computers and are highly reliable. However, their construction is expensive and they are not very suitable for daily use in coat pockets, wallets or ladies' handbags.

Optical CD-ROM's have developed beyond their original read-only status and rewritable CD-ROM's are supplied by several companies, e.g. the Hewlett-Packard RW 8100 series. A modification to the basic idea is available which includes placing a CD-ROM type data recording medium on a flexible card, for example, LaserCard™ from Drexler Technology Corporation, USA. The disadvantage of all CD-ROM products is that the data may be corrupted by scratches. This makes them suitable for home storage of data, e.g. for music or video, but the surface is not sufficiently robust for the worst of daily uses.

Credit cards with magnetic stripes are also well known but have a very limited storage capacity. Also the data may be wiped by magnets such as the types used to attach identification badges. Long lengths of magnetic tape have also been used successfully for storing very large amounts of data and are used daily in the form of cassettes for playing music. However, they have not found favor for personal storage of data.

Next generation banking cards include microprocessors accessible through surface contacts - sometimes called "smartcards". These known devices have a higher memory capacity than a magnetic stripe card but the amount is still limited. The cards are flexible, sealed against moisture and have surface contacts which are not blocked by dust. One disadvantage of the known surface contacts is that high electrical potentials may be generated by static electricity and this may result in loss of data on discharge. To solve this problem card readers have been provided with electrostatic discharge protection as described for instance in US 5,892,216.

Summarizing the above, there is no suitable storage device available for everyday use which is compact, reliable, has a large memory capacity and can be

produced economically.

It is an object of the present invention to provide a digital storage device which is suitable for daily personal use.

It is a further object of the present invention to provide a digital storage device
5 which has more storage capacity than smartcards while maintaining their flexibility and robustness.

It is still a further object of the present invention to provide surface contacts for a memory card which are better protected against electrostatic discharges.

10 SUMMARY OF THE INVENTION

One aspect of the present invention is to integrate components into a thin flexible memory card with an input/output device so that the components can cooperate as a compact unit providing environmental sealing and secure access to several Mbytes of digital data. The present invention includes a card memory device
15 comprising: a microprocessor, a plurality of memory units for storage of digital data, the memory units being embedded in the card memory device and a selecting device for selecting one of the memory units and for routing address information and data to and/or from the selected memory unit, both the microprocessor and the selecting device being embedded in the card memory device. The card memory device has an
20 input/output device (I/O device) for receiving and for transmitting data. It is not anticipated that the form of the I/O device is a limitation on the present invention. For instance, the I/O device may comprise surface contacts for sliding introduction into a card reader. Alternatively, the card may be contactless and the input/output is via electromagnetic radiation such as radio frequency or infra-red transmission. For radio
25 frequency transmissions the input device will generally comprise an antenna embedded in the card. An infra red input device will generally comprise a photovoltaic cell of some kind for receiving the infra red light and for converting it into electrical signals as well as a transmitting device such as an LED (light emitting diode). The power to drive the electronic components of the card may be provided from the incident
30 electromagnetic radiation or may be provided by a battery. A serial port of the microprocessor is connected to the input device, e.g. to one of the surface contacts. Serial data is entered into or read out of the card memory device through the

microprocessor. The microprocessor is preferably a secure single chip microprocessor. A serial data port of the microprocessor is connected to a serial port of the selecting device via a first serial bus. For selecting a memory unit, a parallel port of the selecting device is connected to a parallel port of the microprocessor via a parallel address bus.

5 A parallel portion of a memory storage location (bit) address is output or input via the parallel bus. The selecting device has a plurality of serial ports each one connected to a respective memory unit via a second serial bus. The parallel address portion defines one of the input/output serial ports of the selecting device and its associated serial bus and memory unit. Once the serial bus has been selected the microprocessor then sends
10 serial address information via the first and second busses to define a digital data storage location of the selected memory unit. Memory units may be organized in memory modules, each memory module including a plurality of memory units. Each memory unit may include one or more memory devices, e.g. memory chips.

The present invention also includes a card memory device comprising a first set
15 of surface contacts including a ground contact, a power source contact and a data input and/or output contact, and the first set corresponding to a second set of contacts in a card memory device reader, the ground contact of the first set being arranged to ground any contact of the second set before this reader contact makes contact with any of the power and/or data contacts. The ground contact serves to discharge any
20 electrostatic potential on the card memory device or on the reader. Preferably, the ground contact on the card memory device surrounds the data contact three sides, e.g. it may be "U" shaped. The power contact of the card memory device may close the top of the "U".

The present invention includes the use of the card memory device described
25 above for providing secure access to a personal computer. The present invention includes a method of secure operation of a computing device, comprising the use of a first card memory device having a microprocessor and a reader connected to the computing device for reading the first card memory device, the method comprising the steps of: configuring the operating system of the computing device so that operation is
30 limited unless the card memory device is inserted into the reader; generating one or more codes relating to system information of the computing device; comparing the generated codes with other codes in the first card memory device, the other codes

indicating validated system data for the computing device; and only allowing further unrestricted operation of the computing device if the generated and stored other codes are the same. The first card memory device is preferably a card memory device according the present invention. In particular, it is preferably thin, flexible and environmentally sealed. Preferably the card memory device has an input device which may be sliding contacts in accordance with an embodiment of the present invention. Alternatively, the input device may be contactless, e.g. a radio frequency wireless input device or an infra-red input device. Preferably, the system data includes references to software and/or hardware installed on the computing device. The method also preferably includes a validation step for validating the system data of the computing device. Preferably, if there is no match of codes, a further card memory device may be used to provide authentication to the computing device to update the first card memory device with revised codes. Preferably, the second card memory device is inhibited for further use after the authentication has been transferred a limited number of times, e.g. once. The computing device may be a personal computer or a terminal attached to a LAN or WAN.

The dependent claims each define a separate and individual embodiment of the present invention. The present invention will now be described with reference to the following drawings.

20

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 is a schematic circuit diagram representation of an embodiment of the card memory device in accordance with the present invention.

Fig. 2 is a possible layout of the card memory device of Fig. 1 on a card.

Fig. 3 is a schematic representation of a dispatcher circuit in accordance with an embodiment of the present invention

Fig. 4A shows a parallel four bit addressing scheme for selection of a memory unit in accordance with an embodiment of the present invention.

Fig. 4B shows a three byte serial addressing scheme in accordance with an embodiment of the present invention.

Fig. 5 is a schematic representation of a memory module in accordance with an embodiment of the present invention.

Figs. 6A to 6E show authentication schemes which may be used with the present invention. Fig. 6A shows the authentication scheme between a system and a memory card according to the present invention. Figs. 6B to 6E show a verification scheme for safe installation of software in accordance with an embodiment of the present invention.

Fig. 7 is a schematic representation of a card reader and processing device with which the present invention may be used.

Fig. 8 is a top view of surface contacts suitable for use with the embodiment of the present invention shown in Figs. 1 and 2.

DETAILED DESCRIPTION OF THE ILLUSTRATIVE EMBODIMENTS

The present invention will be described with respect to certain embodiments and to certain schematic drawings but the present invention is not limited thereto but only by the claims. In particular, the card memory device will be described with reference to an 8-bit byte scheme but the present invention is not limited thereto. Further, the present invention will mainly be described with reference to a card memory device with contacts but the present invention is not limited thereto. For instance, the card device may have an input device which receives electromagnetic radiation such as radio frequency transmissions or infra-red transmissions. Where the card receives electromagnetic radiation the card device has a suitable receiver and transmitter, e.g. an embedded antenna or infra-red receiver and transmitter (LED).

Fig. 1 shows a schematic circuit diagram of a data storage device 20 in accordance with an embodiment of the present invention. Fig. 2 shows a possible layout of the card memory device 20 on a card. The device 20 is preferably an environmentally sealed, flexible (plastic) card with an embedded microprocessor 2 and a plurality of embedded memory modules 5-12. The dimensions of card memory device 20 may be similar or identical to those of other flexible "smartcards" such as telephone cards or credit cards which have an embedded microprocessor, e.g. 85 mm by 55 mm by 1 mm thick. The card memory device 20 has an input/output device such as a set 1 of surface contacts 21-25 which serve for connection it to a suitable card reader. The card reader may be a stand-alone reader, or may be included in a personal computer, in a lap-top, in a palm-top, in a terminal connected to a telecommunications network for

communication with a remote computer, or similar. The set 1 of contacts provides power input (Vcc), serial data input/output (SDA), ground potential input (Vss), a clock input (CLK) and a microprocessor reset (RST) connections. The microprocessor 2 is preferably a single chip secure microprocessor of the type SCENIX SX/18 as supplied by SCENIX, USA. Included on the microprocessor chip is preferably read-only memory (ROM) for the storage of application programs and for all operating conditions for the device 20, random access memory (RAM) and optionally non-volatile read/write memory of which at least a part is preferably protected memory for the storing of data required for power up and initialization of the device 20.

10 The power input contact (Vcc) of set 1 is connected to the power input of the microprocessor 2, similarly the ground potential input (Vss), the clock input (CLK) and the microprocessor reset (RST) contacts of set 1 are connected to equivalent pins of the microprocessor 2. The SDA contact of the set 1 is connected directly to the serial data input pin (SDA) of the microprocessor 2. Hence, all data to be read from or
15 written into the memory modules 5-12 passes through the microprocessor 2. To access card memory device 20 a communication session with the microprocessor 2 is set up via the card reader in which communication channels are opened via the SDA contact of set 1 after an authentication procedure (to be described later). It is not expected that the method of authentication is a limit on the present invention. In particular, suitable
20 authentication methods may include the use of public and/or private keys and/or specific session keys as is known to the skilled person. In addition, the present invention may include the requirement that the owner of the card memory device 20 is required to enter one or more personal identification numbers (PIN) at the card reader before authentication and verification is complete. In addition, the present invention
25 may include a restriction on the number of times a PIN may be entered before the card is blocked and further access is denied. In addition, the present invention may include the requirement that the operator of the card reader (different from the owner of the card memory device 20) is additionally or alternatively required to enter a PIN, account, service or system number (either directly through a key pad or indirectly by
30 the transmission of a code number or numbers from the memory of the card reader to the microprocessor 2) so that the microprocessor 2 can verify that the card reader belongs to a group of authenticated card readers allowed to access the data on the card

memory device 20.

Embedded in the card memory device 20 is a plurality of memory modules 5-12 one of which shown best in Fig. 5. These memory modules 5-12 may include volatile, e.g. RAM, or non-volatile read-only such as ROM or read/writable non-volatile memory units 16. The memory units 16 may also be one-time programmable memory units. The memory units 16 of the memory modules 5-12 preferably do not require refresh. The memory modules 5-12 are preferably electrically erasable programable read only memory (EEPROM) modules. Each module 5-12 may be composed of several individual memory units 16, each memory unit 16 comprising a plurality of memories 17, for instance, memory chips, e.g. one module 5-12 may contain four units 16 of eight EEPROM memories 17 each storing 32 or 64 Kbytes of digital data, e.g. 24FC256 memory chips as supplied by Microchip USA, or the 24XA512 chips as supplied by Siemens Germany. Hence, a total storage capacity for each module 5-12 may be $4 \times 8 \times 64 = 2048$ Kbytes and a total for the card memory device 20 of $8 \times 4 \times 8 \times 64$ Kbytes = 16 Megabyte. By changing the memory capacity of each memory module 5-12 or by changing the number of them, the memory capacity of the card memory device 20 may be easily selected between 2 and 16 Mbytes.

To provide power (Vcc), ground (Vss), clock signals (SCL) and write protect (WP) for all memory modules 5-12 a card bus 14 is provided. For the microprocessor 2 to address and to read and write data from and to each memory module 5-12, a system of parallel and serial busses 5-B ... 12-B, 13, 15 is provided. The addressing scheme in accordance with the present invention is a novel hybrid parallel/serial address scheme. Each address of a memory location in a memory module 5-12 is defined by a serial address portion and a parallel address portion. Each memory module 5-12 is provided with a plurality of serial busses 5-B1-4, 6-B1-4, ..., 12-B1-4 for carrying serial data and the serial portion of an address. Each memory unit 16 of each memory module 5-12 has its own unique serial bus 5-B1-4...12B1-4. To select the required serial bus 5-B1-4, ..., 12-B1-4 at least one bi-directional multiplexer-dispatcher 3, 4 is provided. The multiplexer-dispatcher 3,4 is preferably constructed as an application specific integrated circuit (ASIC). The inputs and outputs of a multiplexer-dispatcher 3, 4 are shown in Fig. 3. The inputs from the microprocessor 2 include a serial data connection (SDA) connected to a serial bus 13 for receipt and transmission of serial data to and

from the microprocessor 2 and hence to and from the card memory device 20 as well as receipt and transmission of the serial address portion of addresses for the memory modules 5-12. All communication i.e. selection of memory modules 5-12, selection of EEPROM chips 17 within a module 5-12 and transmission of addresses and serial data are inhibited by the appropriate signal placed by the microprocessor 2 on the INHIBIT connection of the multiplexer-dispatcher 3, 4. Preferably, the INHIBIT pins of multiplexer-dispatchers 3, 4 are ganged so that all multiplexer-dispatchers 3, 4 are inhibited together. This differs from the circuits described in US 5,293,424 in that in these known circuits each memory module includes a lock circuit and so denial of access to one memory module does not prevent access to other memory modules. Also, it differs from the known circuits of US 5,671,367 and US 5,875,480 in which the address bus may be blocked to the memory on the card, but the serial data bus remains open to the memory.

Optionally, after inhibiting the multiplexer-dispatcher(s) 3,4, the microprocessor 2 may write a flag to a register in its protected non-volatile memory so that on power-up of the microprocessor 2, it reads the state of the flag in its memory, and if the flag has been set, microprocessor 2 inhibits the operation of multiplexer-dispatchers 3, 4, i.e. so that power down and power-up will not lift the blocked communication state. A special procedure may be necessary to release the card memory device 20 from its inhibited state.

Parallel pins A, B, C, D of the multiplexer-dispatcher 3, 4 are connected to the parallel bus 15 from the microprocessor 2. These are provided for the parallel portion of the addressing scheme in accordance with the present invention. An appropriate signal (logic 1 or 0) on the FOLLOW pin of the multiplexer 3, 4 prevents a change in the address selected by the dispatcher 3, 4 until the signal changes to the other logical value.

Each multiplexer-dispatcher 3, 4 has 16 serial data outputs 18 labeled SDA0-3 organized in banks of four. Each serial data output 18 is routed to one of the four memory units 16 of a memory module 5-12 via its unique serial bus 5-B1-4....12-B1-4. Each bus 5-B1-412-B1-4 is connected to the respective pin SDA0-SDA3 of the relevant memory module 5-12 and the respective pin SDA0-SDA3 of the multiplexer/dispatcher 3, 4. Which serial bus 5-B1-4....12B1-4 is selected depends on

the parallel portion of the memory card address which is available on the parallel bus 15 from the microprocessor 2. The parallel portion of a memory card address is shown schematically in Fig. 4A. The four bits provide 16 different addresses. For example, 0000 may select the memory unit 16 defined by the bank 0, SDA0 pin of the
5 multiplexer/dispatcher 3. This pin is connected to serial bus 5-B1 and the pin SDA0 of the memory module 5. 1111 selects the memory unit 16 defined by the bank 3, SDA 3 pin of the multiplexer/dispatcher 3 which is connected to the serial bus 8-B4 for connection to the memory unit 8. Hence, the parallel portion of the memory address determines which of the $4 \times 4 = 16$ 512 Kbytes memory units 16 are selected. Each
10 memory unit 16 includes up to 8×64 Kbytes EEPROM memories 17.

The serial portion of the addressing scheme of the card memory device 20 may be as shown in Fig. 4B (3 byte serial address). The first 4 bits of the first byte may be used to define any suitable parameter, e.g. a manufacturer's code, for instance 1010 for the initialisation of the serial port of an EEPROM. The next three bits determine which
15 of the eight 64 Kbytes EEPROM memories 17 is selected from one 512 Kbytes memory unit 16. The final bit of the first byte determines whether a read or write is performed. The next two bytes (the address high and low bytes) determine which of the 64 Kbytes storage locations of a particular memory 17 are to be written or read.

A representative memory module 5 is shown schematically in Fig. 5. Each of
20 the serial busses 5-B1-4 is connected to one of the pins SDA0-3 of the four memory units 16. Each memory unit 16 comprises at least one memory 17. The connections for power (V_{cc} and V_{ss}) to the memories 17 and for the clock input (SCL) are connected to the card bus 14 and hence with the set 1 of contacts. The write protect (WP) pin of the memory module 5 is connected to the respective pin of the microprocessor 2.

25 The card memory device 20 may be operated in several different modes each one of which is a separate embodiment of the present invention. Firstly, the microprocessor 2 may convert each memory address requested via the card reader into the hybrid card address described above using an algorithm. For instance the microprocessor 2 has a resident program stored in its ROM for calculating a hash or
30 one way function. This algorithm may be based on a key which is stored in the ROM or more preferably in the protected read/write memory of the microprocessor 2 at manufacture thereof. The key used for each card memory device may be different even

if the same algorithm is used. On receipt of an address for reading or writing the microprocessor 2 operates on the input address and generates therefrom the four bit parallel portion of the memory card address as well as the three byte serial portion of the memory card address as shown in Figs. 4A and B using hash or one way functions.

5 The microprocessor 2 then uses this encrypted hybrid address for reading or writing the data. By this means the actual data stored in any one memory module 5-12 is pseudorandomly sorted so that attempts to analyze the data on the card 20 by external probes will be fruitless. Further, even if the operation of one card memory device 20 is analyzed it gives no indication of how other cards operate. Firstly, one of the
10 properties of hash functions or one way functions is that it is almost impossible to derive the function from its results. Secondly, the operation of the hash function or one way function depends upon the value of the key stored in the protected memory of the microprocessor 2 so that the address encryption is different for each card memory device 20. Where the memory modules 5-12 are RAM modules, i.e. the data is lost on
15 power down, the key for generating the encrypted addresses may be changed randomly on power-up so that the encrypted addressing differs from session to session.

In a second mode, which may be optionally combined with the first mode, the microprocessor 2 allocates a block of addresses of the memory modules 5-12 when a write request is received. If a later write address is within the same block, the
20 microprocessor 2 selects that block again. If the later requested write address lies outside the first block, the microprocessor 2 creates a second block of addresses. The microprocessor 2 continues with this procedure until all the memory locations of card memory device 20 have been allocated. By this procedure the card memory device 20 can operate with a computer or other microprocessor which has a greater addressing
25 range than is provided by the card memory device 20. By creating blocks, widely differing blocks of addresses of the computer or other microprocessor may be allocated onto the card memory device 20. To keep track of the blocks, i.e. the memory map of the card memory device 20, the microprocessor 2 may record the blocks, their sizes and the addresses to which they correspond in its protected non-volatile read/write
30 memory.

In a third mode of operation, the microprocessor may have a data compression application program stored in its ROM or read/write non-volatile memory. This

application may be called to compress data on writing and to decompress data on reading. The host computer or terminal which includes the card reader for communication with the card memory device 20 does not require knowledge of the compression algorithm which is handled completely by the microprocessor 2.

5 Similarly, in a fourth mode of operation microprocessor 2 may include an encryption and decryption algorithm for encrypting data before writing and decrypting read data. This improves the security of the data on the card 20. Not only is the data then pseudorandomly distributed among the memory modules 5-12 by application of the first mode of operation but also the data is encrypted. The key or keys for the encryption algorithm may be stored in the non-volatile read/write memory of the
10 microprocessor 2 on initialization of the card memory device 20, e.g. during manufacture. Protected read/write memory on the microprocessor chip of the card memory device 20 may be used for temporary storage of intermediate results typically generated by encryption algorithms.

15 To improve the security of the memory card device 20 still further, the microprocessor 2 is preferably programmed to carry out an authentication routine when card memory device 20 is introduced into a card reader. As indicated above, it is not anticipated that the type of authentication will affect the present invention materially.

20 Fig. 6A is a schematic flow diagram of one possible authentication scheme in accordance with an embodiment of the present invention. The memory card 20 is placed in a suitable card reader 31 which is part of a processing device 30 such as a personal computer as shown schematically in Fig. 7. The card reader may be for physically contacting a set of contacts on the card device 20 or it may be a remote
25 reading device such as those which use electromagnetic radiation to communicate. The processing device has a microprocessor 32. Software programs are pre-loaded into the memories of both the processing device 30 and the microprocessor 2 on the card 20. After power-up of the microprocessor 2 via the Vss and Vcc contacts 21, 25 using power supplied from the reader 31, the authentication program starts on
30 microprocessor 2 of the card device 20. The authentication scheme shown in Fig. 6A allows verification of both the card 20 and the processing device 30 as well as the software programs running thereon but the present invention is not limited thereto. For

instance, the verification could be restricted only to the card 20. In step 33, the microprocessor 2 requests the entry of a code A, e.g. a personal identification code (PIN) from the user. The user then inputs the code A. Similarly, the card 20 may request a code B in step 34 from the processing engine 30 in order to check that the processing engine 30 is a verified one. Both code A and B are compared with pre-stored codes in the memory of the microprocessor 2 on card 20 in step 35. If code A is verified as correct the microprocessor 2 on card 20 generates a user acceptance code 36 which is stored for this session. If code B is correct the microprocessor 2 generates a processor acceptance code 37 which is transmitted to the processing device 30. If either of the codes is incorrect, a non-acceptance code is generated and two further entry attempts are permitted. If either of the microprocessor 32 of processing engine 30 or microprocessor 2 are blocked (due to previous fraudulent use) all activity stops. The results of the acceptance code control is finally checked by the processing engine 30 in step 39 and by the microprocessor 2 in step 38. If no correct code A or code B has been entered after three tries the respective one of the microprocessor 2 and the processing device 30 outputs a blocking code A3, B3, respectively and all activity stops. As part of steps 38, 39 a further check is made that the card 20 and/or the processing engine 30 have not been modified in a fraudulent manner. To achieve this the input of further codes 40, 41 are requested from the card 20 and the microprocessor 32 of the processing device 30. Transfer of these codes may occur without user intervention. The codes 40, 41 may be generated by a suitable algorithm from the registry numbers of software programs running on the microprocessor 2 and the microprocessor 32 of processing engine 30 as well as from the reference numbers of hardware such as hard disks. Alternative methods of generating codes 40, 41 using data available in the microprocessor 2 and the processing engine 30 in order to identify any change in the programs running on either are included within the scope of the present invention. Codes 40, 41 may be large in size. They are therefore preferably stored in the memory of the memory modules 5-12 of the card device 20 in accordance with the present invention. Microprocessor 2 on the card device 20 then compares the stored and received codes 40, 41.

If the final check indicates that all codes are correct, access to the programs of the card 20 and the processing engine 30 are allowed in steps 42 and 43 respectively.

In this case final complete acceptance codes 44, 45 are generated.

Fig. 6B is a schematic flow diagram of the use of the card 20 to instantiate a new personal computer 30 and validate its software and/or hardware after purchase in which the processing device 30 is a personal computer shown schematically in Fig. 7.

5 The personal computer 30 is configured for safe access by a user possessing a card memory device 20 in accordance with the present invention. To maintain security the personal computer 30 cannot run unless a validated card 20 is inserted in the reader 31. Card 20 also checks that software running on personal computer is authorized software. When the user purchases the computer he/she is provide with a security card
10 device 48 which may be a card memory device 20 in accordance with the present invention. The card 48 has software programs loaded into the microprocessor 2 for carrying out the verification and validation functions described with respect to the present invention. The user is also provided with one or more "temporary cards" 47. Temporary card 47 may also be a card memory device 20 in accordance with the
15 present invention. The purpose of the temporary card 47 is to allow an update of card 48 with validation data. Once the update is completed the data on card 47 is destroyed and the card is blocked from further use, e.g. by permanently invoking the INHIBIT function mntioned above.

The personal computer 30 is started in step 46 and the operating system halts
20 until a security card 48 is inserted in the reader 31. The card 48 is powered up and the verification program starts to run automatically on microprocessor 2 of card 48. Card 48 requests at least one code A0, B0, C0 from the personal computer 30. The codes A0 B0, C0 are preferably generated by the personal computer 30 from system data on the personal computer 30 which provides an identification of the personal computer
25 and the software running thereon. For example, code A0 may be generated from the number of the BIOS of the personal computer, the code B0 from the number or hardware, e.g. the hard disk of the personal computer and code C0 may be generated from the registration numbers of the software running on the personal computer 30, e.g. the operating system such as Microsoft's "Windows" graphical user interface.
30 Code C0 may be a concatenation of all the other codes A0, B0. The card 48 interrogates its read/write non-volatile memory e.g. like the memory modules 5-12 of a card memory device 20 in accordance with the present invention, to retrieve the code

15

or codes A0, B0, C0. On first instantiation of the personal computer 30 these codes will not be present on card 48. Card 48 then requests insertion of the temporary card 47 into reader 31. Card 48 is then removed from reader 31 and card 47 is inserted. Card 47 provides the authorization to computer 30 to load the codes A0, B0, C0 one
5 time onto card 48. Once computer 30 has received this authorization, all data on card 47 is destroyed and the card is blocked in step 49, e.g. by permanent inhibition using the INHIBIT function described above. Card 48 is substituted for card 47 in the reader 31 and codes A0, B0, C0 are written to the read/write non-volatile memory of card 48. The card 48 is now initialized with the codes A0, B0, C0. Any attempt to change any
10 software running on computer 30 will change one or more of the codes A0, B0, C0 and the card 48 will generate an error message on start-up.

The next start-up of the computer 30 is shown in Fig. 6C. The computer 30 is started in step 51 and the operating system halts until card 48 is inserted in reader 31. Card 48 then checks if it has the required one or more codes A0, B0, C0 stored in its
15 non-volatile memory. Codes A0, B0, C0 represent validated software and/or hardware on computing device 30. As it has been initialized, the card 48 has these codes already stored in the modules 5-12. Card 48 then requests input of the one or more codes A0, B0, C0 from personal computer 30. These codes are generated from the system information of computer 30 as described above and transmitted to card 48 in step 52. In step 53, the received and stored codes A0, B0, C0 are compared by the card 48 and
20 if they are correct the card 48 provides the necessary instructions for the computer 30 to continue operation in step 54. If the codes A0, B0, C0 do not match, the computer 30 is halted in step 55.

To prevent unauthorized cards 48 being used the above scheme may be
25 modified by the addition of a random number RAND which is supplied by the computer 30 as well as the one or more codes A0, B0, C0. If the codes are correct the card 48 operates on the random number with an algorithm such as a one-way function or a hash code. The result Sres of this operation is transmitted to personal computer 30. Personal computer 30 calculates Sres from the random number and the same
30 algorithm. Is the received and calculated Sres match then the computer 30 may continue operation. If card 48 determines that one of codes A0, B0, C0 is incorrect, a random number Srand is generated having the same format as Sres and transmitted to

the computer 30. When computer calculates Sres from RAND and compares with Srand it determines that they are different and operation is blocked.

Fig. 6D is a schematic diagram of how a new software program is installed on a computer as well as validating this software with the security card 48. The software is provided with a further temporary card 47 as described with respect to Fig. 6B. The starting point is an actively running computer having completed step 54 of Fig. 6C. The new software is installed on the computer 30 in step 57. At the end of loading the revised relevant code A0, B0, C0 is calculated from the registration number of the new software. The computer 30 then halts and requests entry of the temporary card 47 in step 58. Card 47 is inserted in reader 31 and provides computer 30 with the necessary authorization to load the revised code or codes A0, B0, C0 onto security card 48. Computer 30 then destroys all data on card 47 in step 59 and card 47 is blocked in step 59, e.g. by permanent setting of the INHIBIT function mentioned above. Card 47 is now removed from reader 31 and card 48 inserted. The computer 30 then writes the new code(s) A0, B0, C0 onto card 48 in step 60. Card 48 is now initialized with the updated codes A0, B0, C0. These represent validated system data for personal computer 30.

The reinstallation of software onto computer 30 is shown schematically in Fig. 6E. Let us assume that due to a virus or for some other reason certain programs have been corrupted on personal computer 30. In 62 the software is reinstalled. In step 63 the relevant code or codes A0, B0, C0 are calculated by personal computer 30 for the re-installed software. This code or codes is checked with the code or codes already stored on the card 48 in step 64. If they agree the operation of computer 30 is continued in step 65. If the codes are incorrect the computer may be halted in step 66 and for example the entry of a temporary card 47 may be requested.

The description above with respect to Figs. 6A to E has been made with reference to a single user and a single personal computer. The above methods and hardware can be extended to include the use of a single security card 48 with a plurality of computers. For example, the employees of a company may be provided with security cards 48 which operate with a group of computers. Each card then has a copy of all the codes A0, B0, C0 for all the computers with which it is to work. By this means a user may log-on to any computer in the group. Further, the use of security card 48 may be

extended for use with a local or wide area network provided the relevant codes identifying the respective LAN, WAN are available and stored on card 48.

Fig. 8 is a schematic top view of surface contacts 21-25 of set 1 for use with the card memory device 20 in accordance with an embodiment of the present invention.

5 Preferably, the ground contact 21 (Vss) is placed on the card in such a way that it enters the card reader first when the card memory device 20 is inserted into the reader. The memory card device 20 is intended to be inserted into a card reader having a slit opening designed to allow sliding entry by memory card device 20 but to prevent entry by other objects. The ground contact 21 is therefore preferably placed closest to one
10 edge of the card memory device compared to the other contacts. 22-25. The ground contact 21 is preferably "U" shaped and encloses the clock signal contact 22 (CLS) the serial data input/output contact 23 (SDA) and the reset contact 24 (RST) on at least three sides. The order of the reset, data input/output and clock contacts 22-24 is not considered to be a limitation on the present invention. The power contact (Vcc) 25
15 may be placed across the top of the "U" of the ground contact 21 as shown in Fig. 8. Preferably the power contact 25 is placed furthest from the side of the card memory device which first enters the card reader. The contacts 21-25 may be made from any suitable material conventionally used for surface contacts of smartcards, credit cards, telephone cards or similar and will usually be a copper alloy. By placing the ground
20 contact 21 in such a position that any metal part of the reader will contact the ground contact 21 first, electrostatic voltages will be discharged and the risk of data loss on the card 20 by electrostatic discharge will be reduced.

The card memory device 20 according to the present invention provides an environmentally sealed memory card of several Mbytes of data (at least 1 MBytes)
25 which may be carried on the person in the usual way like credit cards, e.g. it may be stored in wallets, handbags, coat pockets etc. without loss or corruption. The card memory device 20 in accordance with the present invention may find advantageous use as security cards for controlling the operation of personal computers, as any form of card storing personal data such as health insurance cards, data cards for vehicles, e.g.
30 recording the mileage and driving times of commercial vehicles, as a card for storing computer programs, as a card for storing text documents such as books, etc.

Claims

1. A card memory device having an input/output device and having embedded:
a microprocessor;
5 a plurality of memory units for storage of digital data; and
a selecting device for selecting one of the memory units and for routing the address
information and data to and/or from the selected memory unit, wherein the
microprocessor is interposed between the input/output device and the selecting device
and is adapted for passing through data to be sent from and received by the card memory
10 device and for supplying address information for the data sent to each memory unit.
2. The card memory device according to claim 1, wherein the addressing scheme for
each memory location of a memory unit includes a parallel and a serial portion.
- 15 3. The card memory device according to claim 2, wherein a parallel port of the selecting
device is connected to a parallel port of the microprocessor for receiving the parallel
portion of a card memory address.
4. The card memory according to claim 2 or 3, wherein a first serial port of the selecting
20 device is connected to a serial port of the microprocessor for receiving the serial portion
of a card memory address.
5. The card memory device according to any of claims 2 to 4, wherein the selecting
device has a plurality of second serial ports, one connected to each memory unit via a
25 serial bus and the parallel address portion defines one of the second serial ports of the
selecting device.
6. The card memory device according to any previous claim, wherein the memory
capacity is at least 1 Mbytes.
- 30 7. The card memory device according to any previous claim, wherein the input/output
device comprises a first set of surface contacts including a ground contact, a power

source contact and a data input and/or output contact, and the first set corresponding to a second set of contacts in a card memory device reader, the ground contact of the first set being arranged to contact any one contact of of the second set before this reader contact makes contact with any of the power and/or data contacts.

5

8. The card memory device according to claim 7, wherein the ground contact on the card memory device surrounds the data contact on three sides.

9. A card memory device comprising:

10

a first set of surface contacts including a ground contact, a power source contact and a data input and/or output contact, the first set corresponding to a second set of contacts in a card memory device reader, the ground contact of the first set being arranged to make contact with any contact of the second set before this reader contact makes contact with any of the power and/or data contacts.

15

10. The card memory device according to claim 9, wherein the ground contact on the card memory device surrounds the data contact on three sides.

20

11. A method of secure operation of a computing device, comprising the use of a first card memory device having a microprocessor and a reader connected to the computing device for reading the first card memory device, the method comprising the steps of: configuring the operating system of the computing device so that operation is limited unless the first card memory device is inserted into the reader; generating one or more codes relating to system information of the computing device; comparing the generated codes with other codes in the first card memory device, the other codes representing validated system data for the computing device; and only allowing further unrestricted operation of the computing device if the generated and stored other codes are the same.

25

30

12. The method according to claim 11, wherein the first card memory device is a card memory device according to any of the claims 1 to 10.
